

Capital Budgeting Techniques and Practice

Capital Budgeting: the process of planning for purchases of long-term assets.

□ **example**:

Suppose our firm must decide whether to purchase a new plastic molding machine for \$125,000. How do we decide?

□ Will the machine be **profitable**?

□ Will our firm earn a **high rate of return** on the investment?

Decision-making Criteria in Capital Budgeting

How do we decide if a capital investment project should be accepted or rejected?

Decision-making Criteria in Capital Budgeting

- **The Ideal Evaluation Method should:**
 - a) include all cash flows that occur during the life of the project,
 - b) consider the time value of money,
 - c) incorporate the required rate of return on the project.

Payback Period

- How long will it take for the project to generate enough cash to pay for itself?

Payback Period

- How long will it take for the project to generate enough cash to pay for itself?

Payback Period

- How long will it take for the project to generate enough cash to pay for itself?

Payback period = 3.33 years.

Payback Period

- Is a **3.33 year** payback period good?
- Is it acceptable?
- Firms that use this method will compare the payback calculation to some standard set by the firm.
- If our senior management had set a cut-off of **5 years** for projects like ours, what would be our decision?
- Accept the project.

Drawbacks of Payback Period

- ❑ **Firm cutoffs are subjective.**
- ❑ **Does not consider time value of money.**
- ❑ **Does not consider any required rate of return.**
- ❑ **Does not consider all of the project's cash flows.**

Drawbacks of Payback Period

- Does not consider all of the project's cash flows.

- Consider this cash flow stream!

Drawbacks of Payback Period

- Does not consider all of the project's cash flows.

- This project is clearly unprofitable, but we would accept it based on a 4-year payback criterion!

Other Methods

- 1) **Net Present Value (NPV)**
- 2) **Profitability Index (PI)**
- 3) **Internal Rate of Return (IRR)**

Each of these decision-making criteria:

- **Examines all net cash flows,**
- **Considers the time value of money, and**
- **Considers the required rate of return.**

Net Present Value

- **NPV = the total PV of the annual net cash flows - the initial outlay.**

$$\text{NPV} = \sum_{t=1}^n \frac{\text{ACF}_t}{(1+k)^t} - \text{IO}$$

Net Present Value

- Decision Rule:
- If NPV is positive, **accept.**
- If NPV is negative, **reject.**

NPV Example

- Suppose we are considering a capital investment that costs \$250,000 and provides annual net cash flows of \$100,000 for five years. The firm's required rate of return is 15%.

NPV Example

- Suppose we are considering a capital investment that costs \$250,000 and provides annual net cash flows of \$100,000 for five years. The firm's required rate of return is 15%.

Net Present Value (NPV)

NPV is just the PV of the annual cash flows minus the initial outflow.

Using TVM:

$$\mathbf{P/Y = 1 \quad N = 5 \quad I = 15}$$

$$\mathbf{PMT = 100,000}$$

$$\mathbf{PV \text{ of cash flows} = \$335,216}$$

$$\mathbf{- \text{Initial outflow: } \underline{(\$250,000)}}$$

$$\mathbf{= \text{Net PV} \quad \$85,216}$$

Profitability Index

Profitability Index

$$\text{NPV} = \sum_{t=1}^n \frac{\text{ACF}_t}{(1+k)^t} - \text{IO}$$

Profitability Index

$$\text{NPV} = \sum_{t=1}^n \frac{\text{ACF}_t}{(1+k)^t} - \text{IO}$$

$$\text{PI} = \sum_{t=1}^n \frac{\text{ACF}_t}{(1+k)^t} / \text{IO}$$

Profitability Index

- Decision Rule:
- If PI is greater than or equal to 1, **accept.**
- If PI is less than 1, **reject.**

Internal Rate of Return (IRR)

- **IRR**: the return on the firm's invested capital. IRR is simply the rate of return that the firm earns on its capital budgeting projects.

Internal Rate of Return (IRR)

Internal Rate of Return (IRR)

$$\text{NPV} = \sum_{t=1}^n \frac{\text{ACF}_t}{(1+k)^t} - \text{IO}$$

Internal Rate of Return (IRR)

$$\text{NPV} = \sum_{t=1}^n \frac{\text{ACF}_t}{(1+k)^t} - \text{IO}$$

$$\text{IRR: } \sum_{t=1}^n \frac{\text{ACF}_t}{(1+\text{IRR})^t} = \text{IO}$$

Internal Rate of Return (IRR)

$$\text{IRR: } \sum_{t=1}^n \frac{\text{ACF}_t}{(1 + \text{IRR})^t} = \text{IO}$$

- IRR is the rate of return that makes the **PV of the cash flows** equal to the **initial outlay**.
- This looks very similar to our Yield to Maturity formula for bonds. In fact, **YTM** is the IRR of a bond.

Calculating IRR

- Looking again at our problem:
- The IRR is the discount rate that makes the PV of the projected cash flows equal to the initial outlay.

IRR

- Decision Rule:
- If IRR is greater than or equal to the required rate of return, **accept.**
- If IRR is less than the required rate of return, **reject.**

□ IRR is a good decision-making tool as long as cash flows are conventional.

(- + + + + +)

□ *Problem:* If there are multiple sign changes in the cash flow stream, we could get multiple IRRs. (- + + - + +)

□ IRR is a good decision-making tool as long as cash flows are conventional.

(- + + + + +)

□ *Problem:* If there are multiple sign changes in the cash flow stream, we could get multiple IRRs. (- + + - + +)

□ IRR is a good decision-making tool as long as cash flows are conventional.

(- + + + + +)

□ *Problem:* If there are multiple sign changes in the cash flow stream, we could get multiple IRRs. (- + + - + +)

□ IRR is a good decision-making tool as long as cash flows are conventional.

(- + + + + +)

□ *Problem:* If there are multiple sign changes in the cash flow stream, we could get multiple IRRs. (- + + - + +)

Summary Problem

- Enter the cash flows only once.
- Find the **IRR**.
- Using a discount rate of **15%**, find **NPV**.
- Add back IO and divide by IO to get **PI**.

Summary Problem

- **IRR = 34.37%.**
- **Using a discount rate of 15%,
NPV = \$510.52.**
- **PI = 1.57.**

Capital Rationing

- ❑ **Suppose that you have evaluated 5 capital investment projects for your company.**
- ❑ **Suppose that the VP of Finance has given you a limited capital budget.**
- ❑ **How do you decide which projects to select?**

Capital Rationing

- You could rank the projects by IRR:

Problems with Project Ranking

1) Mutually exclusive projects of unequal size (the size disparity problem)

- The NPV decision may not agree with IRR or PI.
- **Solution:** select the project with the largest **NPV**.

Size Disparity example

Project A

<u>year</u>	<u>cash flow</u>
0	(135,000)
1	60,000
2	60,000
3	60,000

required return = 12%

IRR = 15.89%

NPV = \$9,110

PI = 1.07

Size Disparity example

Project A

<u>year</u>	<u>cash flow</u>
0	(135,000)
1	60,000
2	60,000
3	60,000

required return = 12%

IRR = 15.89%

NPV = \$9,110

PI = 1.07

Project B

<u>year</u>	<u>cash flow</u>
0	(30,000)
1	15,000
2	15,000
3	15,000

required return = 12%

IRR = 23.38%

NPV = \$6,027

PI = 1.20

Size Disparity example

Project A

<u>year</u>	<u>cash flow</u>
0	(135,000)
1	60,000
2	60,000
3	60,000

required return = 12%

IRR = 15.89%

NPV = \$9,110

PI = 1.07

Project B

<u>year</u>	<u>cash flow</u>
0	(30,000)
1	15,000
2	15,000
3	15,000

required return = 12%

IRR = 23.38%

NPV = \$6,027

PI = 1.20

Problems with Project Ranking

2) The time disparity problem with mutually exclusive projects.

- NPV and PI assume cash flows are reinvested at the required rate of return for the project.
- IRR assumes cash flows are reinvested at the IRR.
- The NPV or PI decision may not agree with the IRR.
- **Solution:** select the largest **NPV**.

Time Disparity example

Project A

<u>year</u>	<u>cash flow</u>
-------------	------------------

0	(48,000)
---	----------

1	1,200
---	-------

2	2,400
---	-------

3	39,000
---	--------

4	42,000
---	--------

required return = 12%

IRR = 18.10%

NPV = \$9,436

PI = 1.20

Time Disparity example

Project A	
<u>year</u>	<u>cash flow</u>
0	(48,000)
1	1,200
2	2,400
3	39,000
4	42,000

required return = 12%

IRR = 18.10%

NPV = \$9,436

PI = 1.20

Project B	
<u>year</u>	<u>cash flow</u>
0	(46,500)
1	36,500
2	24,000
3	2,400
4	2,400

required return = 12%

IRR = 25.51%

NPV = \$8,455

PI = 1.18

Time Disparity example

<u>year</u>	<u>cash flow</u>
-------------	------------------

0	(48,000)
---	----------

1	1,200
---	-------

2	2,400
---	-------

3	39,000
---	--------

4	42,000
---	--------

required return = 12%

IRR = 18.10%

NPV = \$9,436

PI = 1.20

Project B

<u>year</u>	<u>cash flow</u>
-------------	------------------

0	(46,500)
---	----------

1	36,500
---	--------

2	24,000
---	--------

3	2,400
---	-------

4	2,400
---	-------

required return = 12%

IRR = 25.51%

NPV = \$8,455

PI = 1.18

Mutually Exclusive Investments with **Unequal Lives**

- Suppose our firm is planning to expand and we have to select 1 of 2 machines.
- They differ in terms of economic life and capacity.
- How do we decide which machine to select?

□ The after-tax cash flows are:

<u>Year</u>	<u>Machine 1</u>	<u>Machine 2</u>
0	(45,000)	(45,000)
1	20,000	12,000
2	20,000	12,000
3	20,000	12,000
4		12,000
5		12,000
6		12,000

□ Assume a required return of 14%.

Step 1: Calculate NPV

□ $NPV_1 = \$1,433$

□ $NPV_2 = \$1,664$

□ So, does this mean #2 is better?

□ No! The two NPVs can't be compared!

Step 2: Equivalent Annual Annuity (EAA) method

- If we assume that each project will be replaced an infinite number of times in the future, we can convert each NPV to an annuity.
- The projects' EAAs can be compared to determine which is the best project!
- **EAA:** Simply annualize the NPV over the project's life.

□ $EAA_1 = \$617$

□ $EAA_2 = \$428$

□ This tells us that:

□ NPV_1 = annuity of \$617 per year.

□ NPV_2 = annuity of \$428 per year.

□ So, we've reduced a problem with different time horizons to a couple of annuities.

□ **Decision Rule:** Select the highest EAA. We would choose machine #1.

Step 3: Convert back to NPV_{∞}

Step 3: Convert back to NPV_{∞}

- Assuming infinite replacement, the EAAs are actually perpetuities. Get the PV by dividing the EAA by the required rate of return.

Step 3: Convert back to NPV_{∞}

- Assuming infinite replacement, the EAAs are actually perpetuities. Get the PV by dividing the EAA by the required rate of return.
- $NPV_{\infty 1} = 617/.14 = \$4,407$

Step 3: Convert back to NPV_{∞}

- Assuming infinite replacement, the EAAs are actually perpetuities. Get the PV by dividing the EAA by the required rate of return.
- $NPV_{\infty 1} = 617/.14 = \$4,407$
- $NPV_{\infty 2} = 428/.14 = \$3,057$

Step 3: Convert back to NPV_{∞}

- Assuming infinite replacement, the EAAs are actually perpetuities. Get the PV by dividing the EAA by the required rate of return.
- $NPV_{\infty 1} = 617/.14 = \$4,407$
- $NPV_{\infty 2} = 428/.14 = \$3,057$
- This doesn't change the answer, of course; it just converts EAA to a NPV that can be compared.
