

# Irreversible Inhibitions

**Dr. Akhilendra Pratap Bharati**  
Assistant Professor  
Department of Life Science and Biotechnology

# Inactivators or Irreversible enzyme inhibitors

**Irreversible enzyme inhibitors**, or inactivators, bind to the enzyme so tightly that they permanently block the enzyme's activity.

# DIPF (Diisopropylphosphofluoridate)

- A diagnostic test for the presence of the active site Ser of serine proteases is its reaction with **DIPF** which **irreversibly inactivates the enzyme**.
- Other Ser residues, including those on the same protein, do not react with DIPF.
- DIPF reacts only with **Ser 195 of chymotrypsin**, thereby demonstrating that this residue is the enzyme's active site Ser.

The reason that DIPF is such an effective inhibitor of serine proteases is because its **tetrahedral phosphate group** makes this compound a **transition state analog**.

**DIP-Enzyme**

# Nerve Poisons

The use of **DIPF** as an enzyme-inactivating agent came about through the discovery that organophosphorus compounds such as DIPF are potent nerve poisons.

The **neurotoxicity of DIPF** arises from its ability to **inactivate acetylcholinesterase**, an enzyme that catalyzes the hydrolysis of acetylcholine:

DIPF is so toxic to humans (death occurs through the inability to breathe) that it has been used militarily as a **nerve gas**.

Related compounds, such as **parathion** and **malathion**, are useful **insecticides** because they are far more toxic to insects than to mammals.

**Parathion**

**Malathion**

# TPCK

- A second catalytically important residue, **His 57**, was discovered through **affinity labeling**. In this technique, a **substrate analog bearing a reactive group specifically binds at the enzyme's active site**, where it reacts to form a stable covalent bond with a nearby susceptible group. **The affinity labeled group(s) can subsequently be isolated and identified.**
- **Chymotrypsin** specifically binds **tosyl-L-phenylalanine chloromethylketone (TPCK)** because of its resemblance to a **Phe residue**. Active site bound TPCK's chloromethylketone group is a **strong alkylating agent**; it reacts only with His 57, thereby inactivating the enzyme.
- **Trypsin**, which **prefers basic residues**, is similarly inactivated by TPCK.

Chymotrypsin

His 57

+

Tosyl-L-phenylalanine  
chloromethylketone (TPCK)

Chymotrypsin

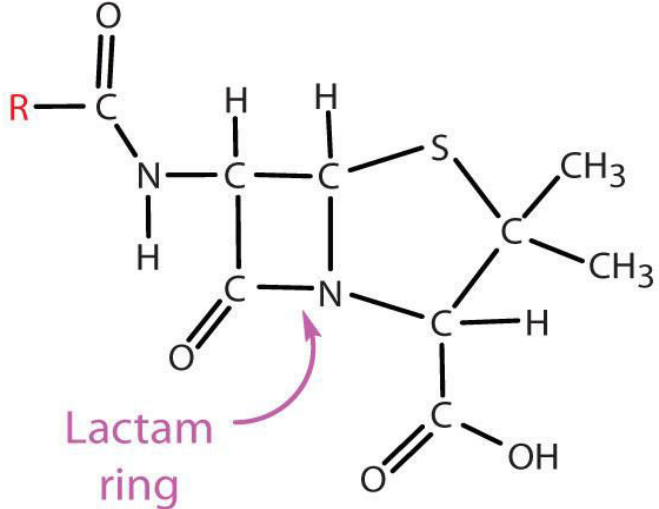

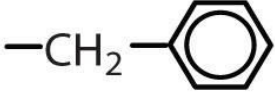

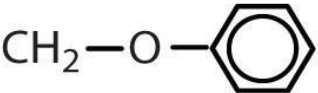

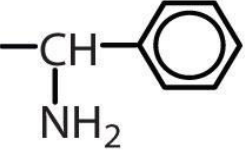

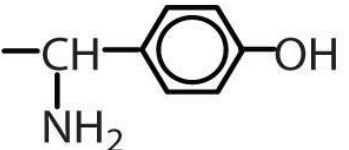

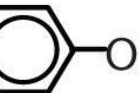

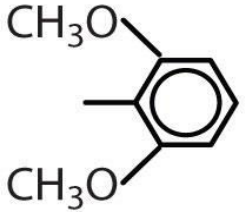

Tosyl-L-lysine chloromethylketone

Trypsin

# Penicillin

Penicillin Structure	R Group	Drug Name
 <p>The diagram shows the general structure of a penicillin molecule. It features a central four-membered beta-lactam ring fused to a five-membered thiazolidine ring. The beta-lactam ring has a carbonyl group (C=O) and a nitrogen atom (N-H). The thiazolidine ring has a sulfur atom (S) and a carbon atom bonded to two methyl groups (CH<sub>3</sub>). A side chain is attached to the nitrogen of the beta-lactam ring, represented as R-C(=O)-. A pink arrow points to the beta-lactam ring with the label "Lactam ring".</p>	 <p>—CH<sub>2</sub>—</p>	penicillin G
	 <p>CH<sub>2</sub>—O—</p>	penicillin V
	 <p>—CH—   NH<sub>2</sub></p>	ampicillin
	 <p>—CH—   NH<sub>2</sub></p>	amoxicillin
	 <p> CH<sub>3</sub>O CH<sub>3</sub>O</p>	methicillin

- 1 Site of action of penicillinase
- 2 Site of action of amidase
- A Thiazolidine ring
- B  $\beta$ -Lactam ring

Active material Raw material for  
other penicillin

Inactive (Major Determinant)  
Responsible for hypersensitivity

# Mechanism of Action

*E. coli* transpeptidation

*S. aureus* transpeptidation

# Iodoacetamide and cysteine proteases
